

# AP CHEMISTRY CHEAT SHEET

## Unit 5 : KINETICS

### Quick Overview

- **Focus:** reaction rates, rate laws, integrated rate laws, activation energy, and reaction mechanisms.
- **Exam Lens:** connect experimental data → rate law → mechanism → energy profile.

### Reaction Rate Basics

- Reaction rate = change in concentration per unit time.
- Rate is always positive.
- **Units of rate:**  $\text{mol}\cdot\text{L}^{-1}\cdot\text{s}^{-1}$  (M/s).
- Rate depends on temperature, concentration, surface area, catalysts, and nature of reactants.

### Rate Laws

#### General rate law:

$$\text{rate} = k[\text{A}]^m[\text{B}]^n$$

- $m, n$  = reaction orders (determined experimentally, not from coefficients).
- Overall order =  $m + n$ .
- Zero order → rate independent of concentration.
- First order → rate  $\propto [\text{A}]$ .
- Second order → rate  $\propto [\text{A}]^2$  or  $[\text{A}][\text{B}]$ .

**Key rule:** Doubling concentration increases rate by  $2^m$ .

### Determining Rate Laws (Method of Initial Rates)

- Compare trials where only one reactant changes.
- Ignore coefficients in balanced equation.
- Rate ratio = (concentration ratio) <sup>$m$</sup> .

**Mnemonic:** "Change one thing, watch the rate."

### Integrated Rate Laws

Used to determine concentration at time  $t$ .

#### Zero Order:

- $[\text{A}] = -kt + [\text{A}]_0$
- Straight line:  $[\text{A}]$  vs  $t$

#### First Order:

- $\ln[\text{A}] = -kt + \ln[\text{A}]_0$
- Straight line:  $\ln[\text{A}]$  vs  $t$

#### Second Order:

- $1/[\text{A}] = kt + 1/[\text{A}]_0$
- Straight line:  $1/[\text{A}]$  vs  $t$

### Half-Life

Time for concentration to drop to half its initial value.

- **First order only:**  
 $t_{1/2} = 0.693 / k$
- Independent of initial concentration.
- Zero and second order half-lives change over time.

**Mnemonic:** "Only first is constant."

### Rate Constant (k)

- Larger  $k \rightarrow$  faster reaction.
- Units depend on overall order:
  - Zero: M/s
  - First:  $\text{s}^{-1}$
  - Second:  $\text{M}^{-1}\cdot\text{s}^{-1}$

$k$  increases with temperature.

### Collision Theory

#### For a reaction to occur:

1. Particles must collide.
2. Collision must have enough energy ( $\geq E_a$ ).
3. Correct orientation required.

Catalysts lower activation energy, not  $\Delta H$  or  $\Delta G$ .

### Activation Energy & Arrhenius Equation

#### Arrhenius equation:

$$k = A \cdot e^{(-E_a / RT)}$$

#### Linearized form:

$$\ln k = -(E_a / R)(1/T) + \ln A$$

- $E_a$  = activation energy
- $R = 8.314 \text{ J}\cdot\text{mol}^{-1}\cdot\text{K}^{-1}$
- Slope of  $\ln k$  vs  $1/T = -E_a / R$

### Reaction Energy Diagrams

- Reactants  $\rightarrow$  peak  $\rightarrow$  products.
- Peak height = activation energy.
- **Exothermic:** products lower than reactants.
- **Endothermic:** products higher than reactants.
- Catalyst lowers  $E_a$  for both forward and reverse reactions.

### Reaction Mechanisms

- Series of elementary steps.
- Slow step = rate-determining step.
- Rate law comes from slow step only.
- Overall reaction = sum of elementary steps.

#### Key rule:

Intermediates appear in mechanism but not overall equation.

### Catalysts

- Provide alternative pathway with lower  $E_a$ .
- Not consumed.
- Do not affect equilibrium position.
- Increase forward and reverse rates equally.
